1. Write a new Java class called `Student`. An object of this type includes attributes for first name, last name, user name (lastname.firstname), ID number, birthdate, and GPA. You must include a constructor that assigns values to all of the attributes, getters and setters for first name, last name and ID number. Additional methods include `getEmail`, which returns the student's email address (username@uwlax.edu) and `toString`, which returns a `String` representation of all attributes in an easy to read format.
