

# Indexes

- Additional data structure used to reduce the pages accesses necessary to find a row or rows
- Search Key
- Search Key is not necessarily unique
- Location Mechanism
  - Algorithm+Data Structure

# Extendable Hashing

- Type of hashing that eliminates chains of pages caused by collisions
- Range of hash function has to be extended to accommodate additional buckets
- **Example:** family of hash functions based on  $h$ :
  - $h_k(v) = h(v) \bmod 2^k$  (use the last  $k$  bits of  $h(v)$ )
  - At any given time a unique hash,  $h_k$ , is used depending on the number of times buckets have been split

# Extendable Hashing - Example

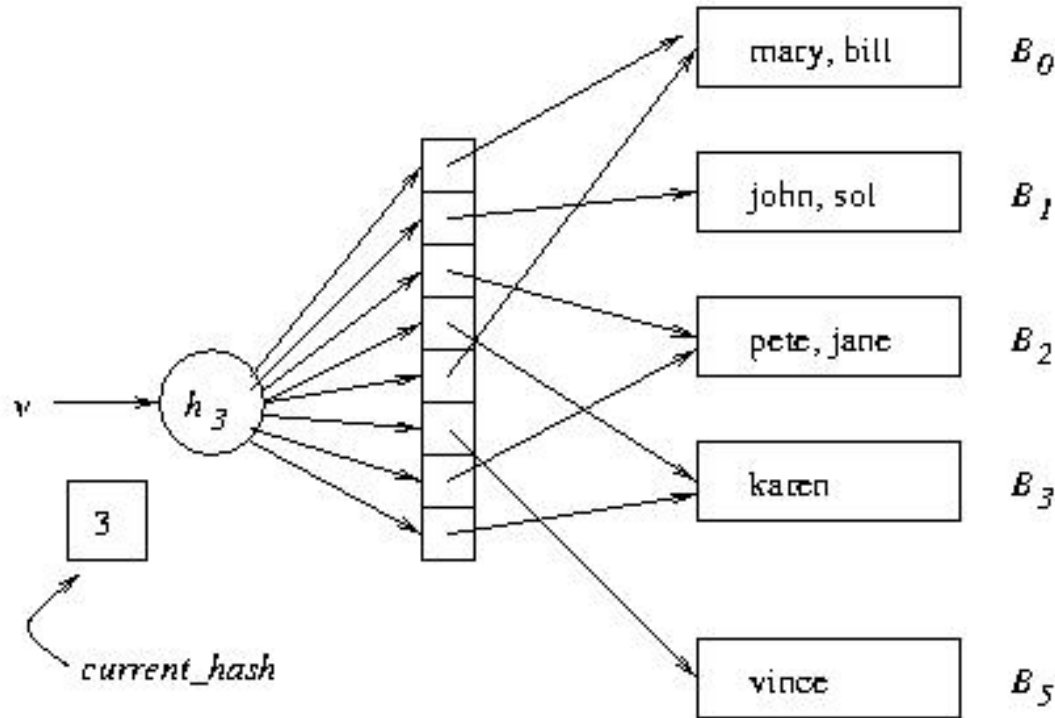

Extendable hashing uses a directory (level of indirection) to accommodate family of hash functions

Suppose next action is to insert sol, where  $h(sol) = 10001$ .

**Problem:** This causes overflow in  $B_1$

# Example (cont'd)

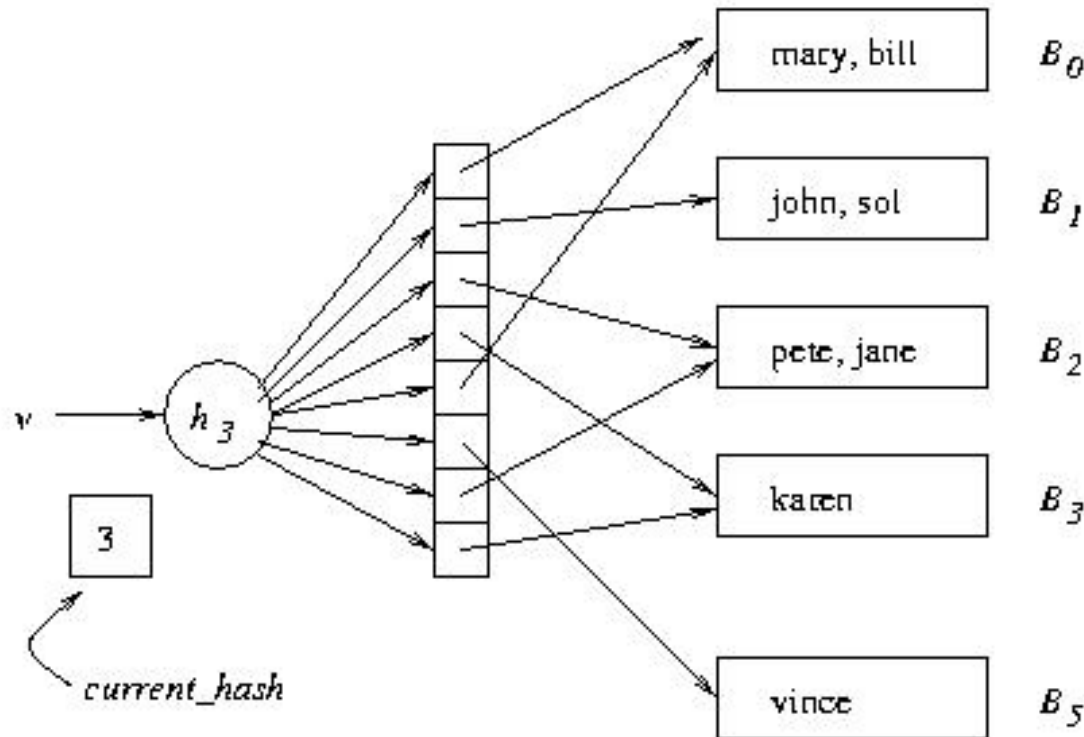

## Solution:

1. Switch to  $h_3$
2. Concatenate copy of old directory to new directory
3. Split overflowed bucket,  $B$ , into  $B$  and  $B'$ , dividing entries in  $B$  between the two using  $h_3$
4. Pointer to  $B$  in directory copy replaced by pointer to  $B'$

Note: Except for  $B'$ , pointers in directory copy refer to original buckets.

*current\_hash* identifies current hash function.

## Example (cont'd)

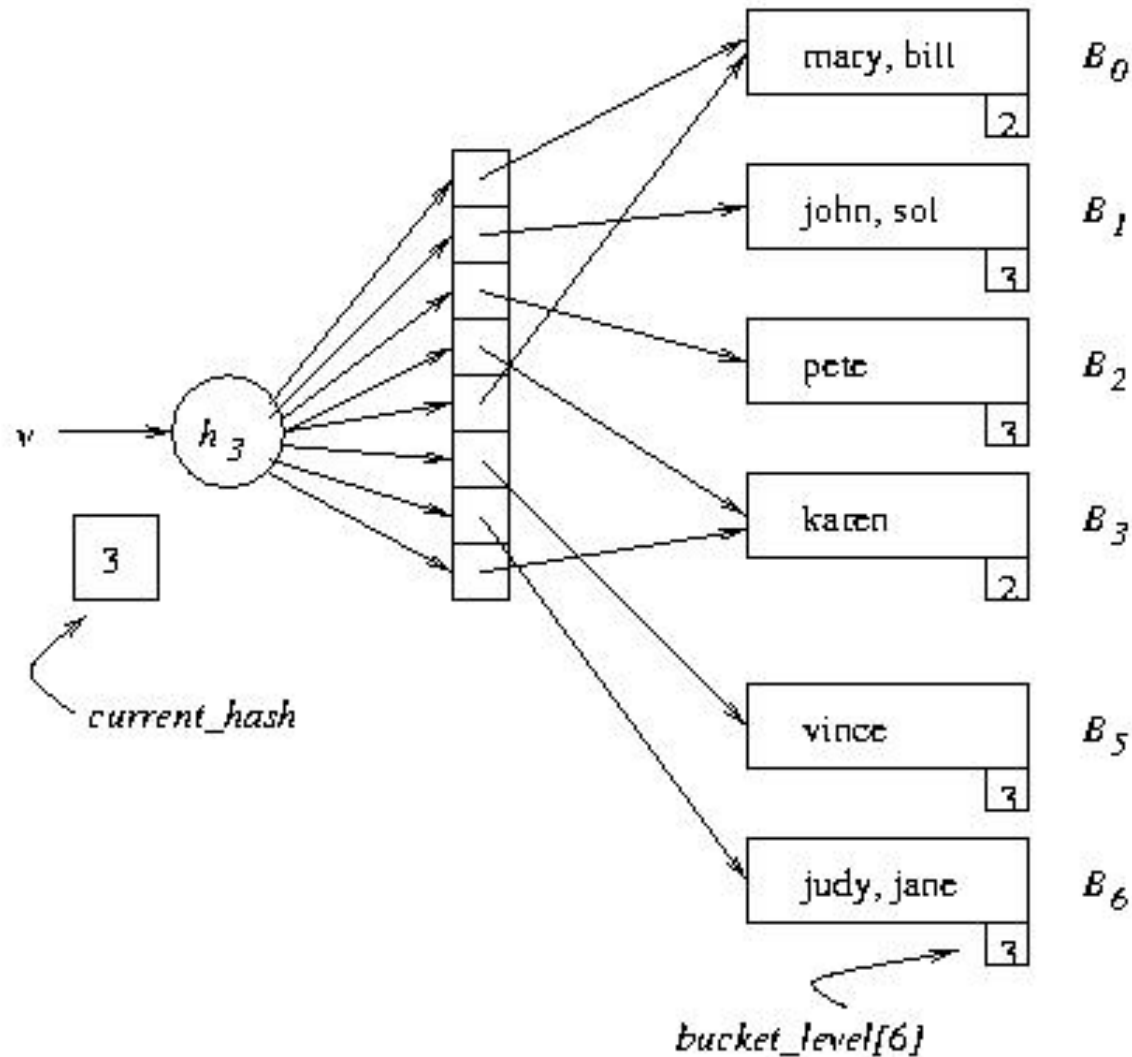

Next action: Insert judy,  
where  $h(judy) = 00110$   
 $B_2$  overflows, but directory  
need not be extended

**Problem:** When  $B_i$  overflows, we need a mechanism for deciding whether the directory has to be doubled

**Solution:**  $bucket\_level[i]$  records the number of times  $B_i$  has been split. If  $current\_hash > bucket\_level[i]$ , do not enlarge directory

# Example (cont'd)

# Extendible Hashing Problem

What does an extendible hash table with a bucket size of 2 look like after the following values are inserted? Assume the starting table has 2 buckets and used  $h_1$

<u>Key</u>	<u>Hash Value</u>
10	100010
323	101001
90	111011
80	001101
37	110111
205	010100
100	000110
120	110110
